Anagrams

The problem

Given a words.txt file containing a newline-delimited list of dictionary words, please implement the Anagrams class so that the get_anagrams() method returns all anagrams from words.txt for a given word.

Bonus requirements:

- Optimise the code for fast retrieval
- Write more tests
- Thread safe implementation

General approach

"An anagram is direct word switch or word play, the result of rearranging the letters of a word or phrase to produce a new word or phrase, using all the original letters exactly once" (source: wikipedia)

That means that in order to get all the anagrams for a given word, we don't need to compare the words their selves but their ordered representation.

Given two words, word1 and word2

If the ordered characters of word1 are the same that the ordered characters of word2,

Then

word1 and word2 are anagrams.

Assumptions

- One given word is anagram of itself.
- Anagrams are **not** case sensitive so "Star" is an anagram of "Rats".
- Special characters as " ' " are considered as regular characters too.

Solutions

There is a few options to approach this problem, and this document goes through some of them, from the one which could come first to an inexperienced developer's head to a couple of them with important improvements.

Well see that the first approach, which implements the trivial solution, has am awful performance, while the second and third one performs thousands of times better with a cost of some extra memory use.

Solution 1: Brute force

This approach collects all the words in the dictionary and stores them in a list. In order to find the anagrams for a given word, the algorithm needs to sort each of the words in the dictionary to compare them to the sorted given word.

The building of the list is very fast, as no operation involved. However, further searches are very slow due to the dictionary needs to be completely walked in order to find anagrams.

```
 89 class Anagrams1(Anagrams):
 90     """
 91     Very poor performance: This approach collects all the words in the
 92     dictionary and stores them in a list.
 93     In order to find the anagrams for a given word, the algorithm needs
 94     to sort each of the words in the dictionary to compare them to the
 95     sorted given word.
 96     """
 97 
 98     def __init__(self, source):
 99         Anagrams.__init__(self, source)
100         self.words = [w[:-2].lower() for w in open(self.source).readlines()]
101 
102     @timing
103     def get_anagrams(self, word):
104         anagrams = []
105         word = "".join(c for c in sorted(word.lower()))
106         for w in self.words:
107             if len(w) != len(word):
108                 continue
109             if "".join(c for c in sorted(w)) == word:
110                 anagrams.append(w)
111         return anagrams
112 
```

Solution 2: sorted characters keys

In this solution, a python dictionary is created in order to store a pair keys - values, where key is the ordered characters representation of each word in the original dictionary and value is a list containing all the words in the original dictionary where their ordered characters representation is the same that the key.

```
115 class Anagrams2(Anagrams):
116     """
117     Much better performance: Create a python dictionary where for each
118     original word in the words dictionary, it stores:
119          - key: the original sorted word
120          - value: all the words that once ordered are the same.
121     """
122 
123     def __init__(self, source):
124         Anagrams.__init__(self, source)
125         self.words = {}
126         with open(self.source) as words:
127             for word in [w[:-2].lower() for w in words]:
128                 key = "".join(c for c in sorted(word))
129                 self.words.setdefault(key, [])
130                 self.words[key].append(word)
131 
132     @timing
133     def get_anagrams(self, word):
134         key = "".join(c for c in sorted(word.lower()))
135         return self.words.get(key, [])
136 
```

Results

Solution 1, as expected, has a very bad performance.

Running each of the approaches 500 times, Solution 1 is between 5000 and 8000 times slower than Solution 2 and Solution 3

ta/tb	Solution 1	Solution 2
Solution1	7763.218794	7645.291891
Solution2		0.984810

Solution 2 performance shows much better performance, due to the fact that searching in a Python dictionary (where keys are hashes) is very efficient.

Figure 1 represents the times for the two solutions.

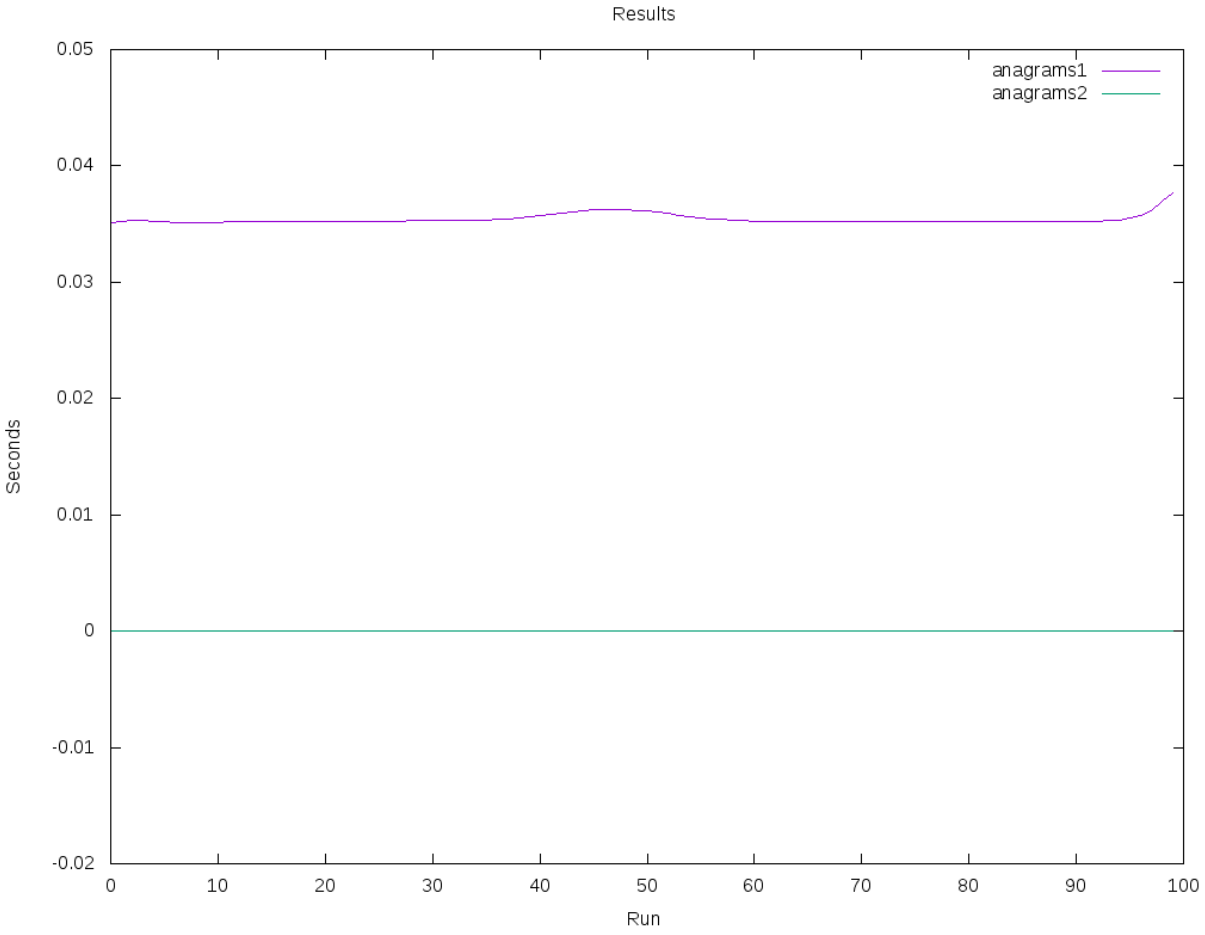

Fig. 1: 100 run times, solutions 1 and 2

Figure 2 represents times for solution 2.

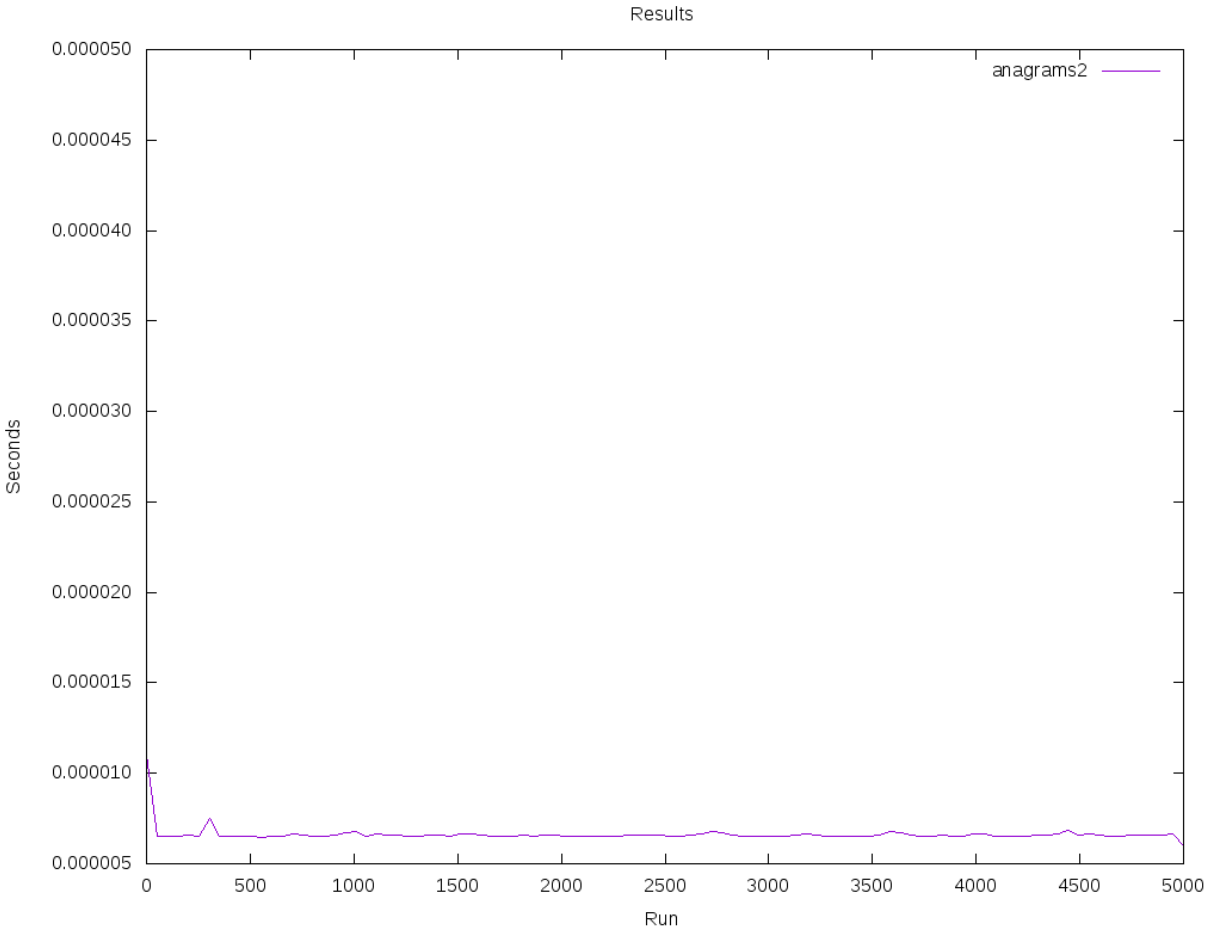

Fig. 2: 5000 ran times, solution 2

Latest considerations

- About tests

  Exhaustive tests are running against every single word in the provide dictionary
- About threading

  All solutions are thread safe
- About performance

  Solutions 2 has a very good performance.

Test environment

- Intel(R) Core(TM) i5-5300U CPU @ 2.30GHz.
- Linux Mint 17
- Python 2.7.6

Appendix

Complete code is bellow:

```
#!/usr/bin/python

"""
Given a words.txt file containing a newline-delimited list of dictionary
words, please implement the Anagrams class so that the get_anagrams() method
returns all anagrams from words.txt for a given word.

**Bonus requirements:**

  - Optimise the code for fast retrieval
  - Write more tests
  - Thread safe implementation
