

# Anagrams

## The problem

Given a words.txt file containing a newline-delimited list of dictionary words, please implement the Anagrams class so that the get\_anagrams() method returns all anagrams from words.txt for a given word.

### Bonus requirements:

- Optimise the code for fast retrieval
- Write more tests
- Thread safe implementation

## General approach

*"An anagram is direct word switch or word play, the result of rearranging the letters of a word or phrase to produce a new word or phrase, using all the original letters exactly once" ( source: wikipedia )*

That means that in order to get all the anagrams for a needed word, we don't need to compare the words themselves but their ordered representation.

Given two words, word1 and word2

If the ordered characters of word1 are the same that the ordered characters of word2,

Then

word1 and word2 are anagrams.

## Assumptions

- One given word is anagram of itself.
- Anagrams are **not** case sensitive so "Star" is an anagram of "Tras".
- Special characters as " ' " are considered as regular characters too.

# Solutions

There is a few options to approach this problem, and this document goes through some of them, from the one which could come first to an inexperienced developer's head to a couple of them with important improvements.

We'll see that the first approach, which implements the trivial solution, has an awful performance, while the second and third one performs thousands of times better with a cost of some extra memory use.

## Solution 1: Brute force

This approach collects all the words in the dictionary and stores them in a list. In order to find the anagrams for a given word, the algorithm needs to sort each of the words in the dictionary to compare them to the sorted given word.

The building of the list is very fast, as no operation involved. However, further searches are very slow due to the dictionary needs to be completely walked in order to find anagrams.

```

97 class Anagrams1(Anagrams):
98     """
99     Very poor performance: This approach collects all the words in the
100     dictionary and stores them in a list.
101     In order to find the anagrams for a given word, the algorithm needs
102     to sort each of the words in the dictionary to compare them to the
103     sorted given word.
104     """
105
106     def __init__(self, source):
107         Anagrams.__init__(self, source)
108         self.words = [w[:-2].lower() for w in open(self.source).readlines()]
109
110     @timing
111     def get_anagrams(self, word):
112         anagrams = []
113         word = "".join(c for c in sorted(word.lower()))
114         for w in self.words:
115             if len(w) != len(word):
116                 continue
117             if "".join(c for c in sorted(w)) == word:
118                 anagrams.append(w)
119         return anagrams
120
```

## Solution 2: sorted characters keys

In this solution, a python dictionary is created in order to store a pair keys - values, where key is the ordered characters representation of each word in the original dictionary and value is a list containing all the words in the original dictionary where their ordered characters representation is the same that the key.

In this case, collecting the words from the original words dictionary is slightly slower and it requires extra memory ( more or less twice, actually ) but the performance later on, getting the anagrams for a given word is much better as only indexing the characters ordered representation of the given word will return all its anagrams.

```
123 class Anagrams2(Anagrams):
124     """
125     Much better performance: Create a python dictionary where for each
126     original word in the words dictionary, it stores:
127         - key: the original sorted word
128         - value: all the words that once ordered are the same.
129     """
130
131     def __init__(self, source):
132         Anagrams.__init__(self, source)
133         self.words = {}
134         with open(self.source) as words:
135             for word in [w[:-2].lower() for w in words]:
136                 key = "".join(c for c in sorted(word))
137                 self.words.setdefault(key, [])
138                 self.words[key].append(word)
139
140     @timing
141     def get_anagrams(self, word):
142         key = "".join(c for c in sorted(word.lower()))
143         return self.words.get(key, [])
144
```

## Solution 3: hash keys

Similarly to solution 2, builds a python dictionary where the key is the hash of the ordered characters representation for each of the original words and value is a list containing all words where the hash of their ordered characters representation matches the key.

This one should be the best approach in performance and the extra memory used for the keys is fixed to *size of integer* \* number of words.

```
147 class Anagrams3(Anagrams):
148     """
149     Hash keys: Create a python dictionary where for each
150     original word in the words dictionary, it stores:
151     - key: the hash of the original sorted word
152     - value: all the words that once ordered have the same hash.
153     """
154
155     def __init__(self, source):
156         Anagrams.__init__(self, source)
157         self.hashes = {}
158         with open(self.source) as words:
159             for word in [w[:-2].lower() for w in words]:
160                 key = hash("".join(c for c in sorted(word)))
161                 self.hashes.setdefault(key, [])
162                 self.hashes[key].append(word)
163
164     @timing
165     def get_anagrams(self, word):
166         key = hash("".join(c for c in sorted(word.lower())))
167         return self.hashes.get(key, [])
168
```

## Results

Solution 1, as expected, has a very bad performance.

Running each of the approaches 500 times, Solution 1 is between 5000 and 8000 times slower than Solution 2 and Solution 3

ta/tb	Solution 1	Solution 2	Solution 3
Solution1		7763.218794	7645.291891
Solution2			0.984810

Solution 2 and Solution 3 are almost the same, being Solution 2 slightly faster than Solution 3 (probably because of the cost of hash).

Solution 3 is, however, less memory consuming.

Figure 1 represents the times for the three solutions.

*Fig. 1: 100 run times, solutions 1, 2 and 3*

Figure 2 represents times for solutions 2 and 3. Both solutions present a very similar performance.

*Fig. 2: 5000 ran times, solutions 2 and 3*

Having a look to these results, the election of Solution 2 or Solution 3 would depend on which is more important in a real project:

- Is it critical to be as fast as possible and to use more memory is not a big deal ?

Solution 2 wins.

- Is it critical to save memory and having a slightly slower algorithm is suitable ?

Solution 3 wins.

## Latest considerations

- About tests

An exhaustive test is run covering 100% of the words in the given dictionary

- About threading

All solutions are thread safe

- About performance

Solutions 2 and 3 have a very good performance.

## Test environment

- Intel(R) Core(TM) i5-5300U CPU @ 2.30GHz.
- Linux Mint 17
- Python 2.7.6

# Appendix

Complete code is bellow:

Note: exhaustive tests are massive so they are in a separated file exhaustive.py

```
1 #!/usr/bin/python
2
3 """
